

DATA QUALITY ASSESSMENT

Olist Brazilian E-Commerce Analytics Project

1. Validation Summary

Dataset	Rows	Columns	Missing Values	Duplicate Rows
Customers	99,441	5	0	0
Orders	99,441	9	7,873	0
Order Items	112,650	7	0	0
Products	32,951	9	2,448	0
Payments	103,886	5	0	0
Reviews	99,224	7	145,903	0
Sellers	3,095	4	0	0

2. Key Quality Observations

Customers, order items, payments, and sellers have no reported missing values or duplicate rows in the statistical validation summary. Orders, products, and reviews contain missing values that were identified during data-quality assessment.

3. Review Dataset Note

The Statistical Analysis Report records 99,224 review rows. The MySQL analytical table was validated separately at 99,222 rows. This discrepancy was investigated during SQL work; the main reviews table remains usable for the completed analysis.

4. Statistical Data Quality

Revenue, product price, freight, delivery delay, and review-score distributions were assessed. Revenue outliers were evaluated using the IQR method, with an outlier percentage of 7.9575%.

5. Interpretation Controls

Negative delivery delay values represent delivery earlier than the estimated date. Pearson price–freight correlation is 0.4142 and is interpreted as association, not causation.

6. Limitations

The documented Mann–Whitney U analysis does not contain the numerical statistic or p-value, so statistical significance is not claimed. Delivery-review relationships are descriptive because no formal association/causal test is documented.
